Acute Traumatic Coagulopathy: Initiated by Hypoperfusion

Modulated Through the Protein C Pathway?

Karim Brohi, FRCS, FRCA, Mitchell J. Cohen, MD,* Michael T. Ganter, MD,†*
Michael A. Matthay, MD,‡ Robert C. Mackersie, MD, and Jean-François Pittet, MD†‡*

- Study at San Francisco General Hospital
- Ann Surg 245:812-818,

- 209 severely traumatized patients admitted to SFGH

- Median time injury – hospital admission: 28 minutes

- If patients were severely injured (ISS>15) and hypoperfused (BD >6) they were coagulopathic.

Coagulopathy after trauma

- Acute traumatic coagulopathy (ATC)
  - 25-33% of patients
  - Worse outcomes:
    - Higher transfusion requirements
    - Longer ICU & hospital stay
    - Higher incidence of multiorgan failure
    - 4-fold higher mortality: 10.9 vs. 46%
- Associated with multiple biochemical mechanisms and phenotypes.
  - Systemic anticoagulation
  - Dysregulated fibrinolysis
  - Platelet dysfunction
- Equally important is endothelial dysfunction.

DIFFERENT AND DYNAMIC PHENOTYPES REQUIRE DIFFERENT RESUSCITATION

Trauma immunology…the quick and dirty

- Trauma kills.
- Patients die from coagulopathy and bleeding.
- But truly they die and suffer from thromboinflammaiton.

- Whole blood has not solved the problem.
- We need personalized treatment.
- Shelf stable individualized resuscitation in a syringe
- Or even better pre deployed in a trauma vaccine

What problem are we trying to solve when we resuscitate?

- Stop bleeding/progression?
- Treat coagulopathy?
- Prevent coagulopathy?
- Treat endotheliopathy?
- Prevent endotheliopathy?

- It is not the same in every patient and not the same minute to minute.

Big audacious science…

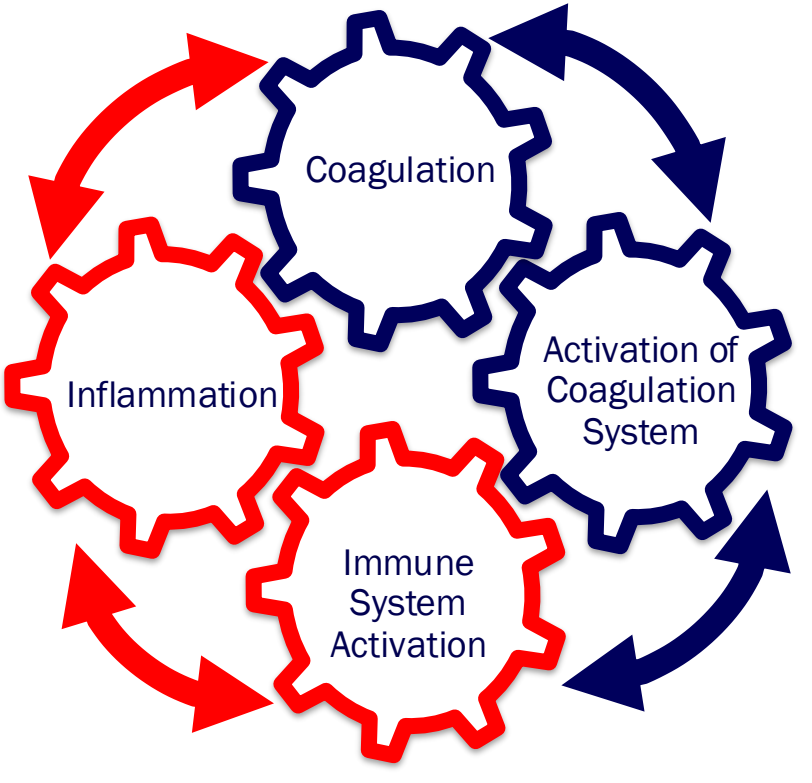
And a TEAM!!

TACTIC – a brief history

- TACTIC was funded from 2013-present by NHLBI, with periodic supplements from BARDA
- Mechanistic studies that dovetail with ongoing clinical trauma trials:
  - Control of Major Bleeding After Trauma: **COMBAT**
  - Prehospital Air Medical Plasma Trial: **PAMPer**
  - Study of Tranexamic Acid during Air Medical Prehospital Transport: **STAAMP**
- Basic science investigators in multiple US sites probed pathways activated in trauma that drive coagulopathy and end organ damage:
  - Novel DAMPs released in trauma
  - Trauma-induced endothelial injury and inflammation
  - Trauma-induced alterations in platelet function
  - Inflammatory mechanisms driving tissue factor expression
  - Multi-omics approaches to identify new players in TIC

What did we learn from TACTIC?

- Critical role of innate immune activation, complement and DAMPs
- Multiple phenotypes of TIC
- Disease of thromboinflammation
- Endothelial activation and injury
- Transfusion of thawed plasma saves lives



CRITICAL UNMET NEED:

- **DRIVERS and EFFECTORS of endothelial injury**
- **Crosstalk between coagulation, inflammation, and immunity**
- **How do we repair/resuscitate the endothelium?**

Team Science

Principal Investigators

Matthew D. Neal, MD
Trauma surgeon
Expertise: Hemostasis, platelet function, coagulation assessment, extracellular vesicles, animal models of trauma

Mitchell Cohen, MD
Trauma surgeon
Expertise: Coagulation biology, endothelial biology, thromboinflammation, protein C, animal models of trauma, computational modeling

Michael Yaffe, MD PhD

Endothelium: the regulator of maladaptive responses and a crucial interface for thrombosis-inflammation crosstalk

- **Central hypothesis:** the synergy of tissue injury and shock after severe trauma leads to by-products of vascular thrombo-inflammation that contribute to the phenotype of coagulopathy, tissue injury and organ failure through a progression to maladaptive endothelial injury; drivers and effectors of endothelial injury can be targeted to direct blood vessel endothelium towards reparative pathways.

How to study a problem: Thromboinflammation

The endotheliopathy of trauma

Endotheliopathy of Trauma (EoT)

- Injured and shocked patients suffer from trauma induced coagulopathy (TIC)
  - ↑ bleeding, ↑ morbidity, ↑ mortality
- Abundant literature on TIC, less to define and identify endotheliopathy
- Thromboinflammation → endotheliopathy, which impacts all patients
  - Creates ICU phenotype → MODS, ↑ ventilator time, ↑ infection
- Results in endothelial permeability

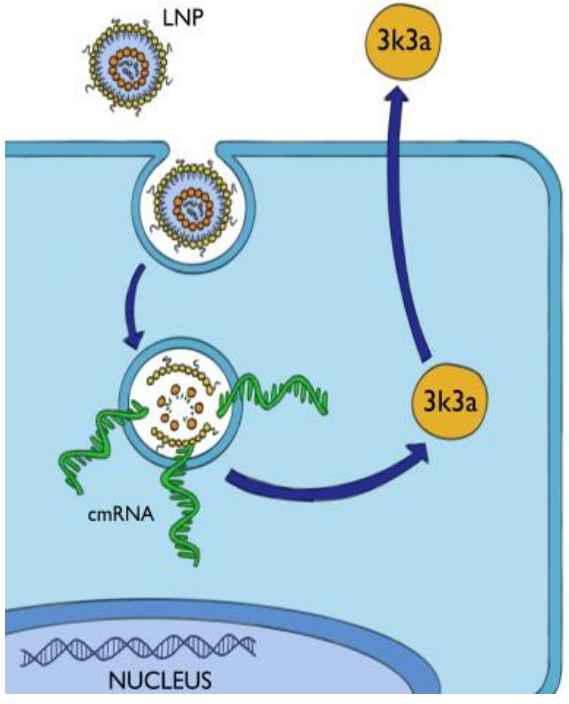
“Next-Gen” mRNA Vaccines for Trauma: Overview

Lipid nanoparticle mRNA delivery of cell-signaling selective activated Protein C: “Next-Gen” precision immunotherapy for thromboinflammatory modulation in trauma.

3K3A-activated protein C (APC), an engineered cell-signaling analogue of the serine protease APC, has cytoprotective effects in brain injury and ischemia and is *currently in phase III human trials* as a neuroprotectant for patients with ischemic stroke. We are studying 3K3A-APC as a novel drug to prevent endothelial dysfunction and immune storm, mitigate TIC, and help set the ‘inflammatory thermostat’ allowing causalities sufficient time to reach definitive care and achieve recovery without thromboinflammatory morbidity and mortality. As a therapeutic, 3K3A-APC can be shelf stable and administered early and far forward even in an autoinjector self given by the injured. This makes it an ideal *‘resuscitation in a syringe’* providing TIC mitigating and inflammamodulatory treatment directly after injury. While treatment after injury will provide benefit, successful prophylactic delivery of therapeutic levels of protective recombinant proteins to at-risk military personnel immediately before deployment with mRNA vaccines will herald the **next generation of precision therapeutics custom-designed to protect troops** from any specific acute threat including not only polytrauma but also exposure to chemicals, radiation, or pathogens. Building on recent advances in mRNA vaccines and materials science, we are conducting a preclinical trial of mRNA/LNPs designed to deliver payloads of 3K3A-aAPC for treatment of endotheliopathy and TIC in polytrauma. <u>This novel mRNA therapeutic will provide a shelf-stable immune modulator and “trauma vaccine” delivering endothelial and immune therapy in a single dose administered (1) immediately after injury or (2) prophylactically to at-risk military personnel before deployment.</u>



Endotheliopathy of Trauma: Calcium Signaling

Combining mechanism, prediction and precision care.

COAGULATION

Targeted clinical control of trauma patient coagulation through a thrombin dynamics model

Amor A. Menezes,[1,2] Ryan F. Vilardi,[3] Adam P. Arkin,[1,2,4]* Mitchell J. Cohen[5,6]*

We present a methodology for personalizing the clinical treatment of severely injured patients with acute traumatic coagulopathy (ATC), an endogenous biological response of impaired coagulation that occurs early after trauma and shock and that is associated with increased bleeding, morbidity, and mortality. Despite biological characterization of ATC, it is not easily or rapidly diagnosed, not always captured by slow laboratory testing, and not accurately represented by coagulation models. This lack of knowledge, combined with the inherent time pressures of trauma treatment, forces surgeons to treat ATC patients according to empirical resuscitation protocols. These entail transfusing large volumes of poorly characterized, nontargeted blood products that are not tailored to an individual, the injury, or coagulation dynamics. Massive transfusion mortality remains at 40 to 70% in the best of trauma centers. As an alternative to blunt treatments, time-consuming tests, and mechanistic models, we used dynamical systems theory to create a simple, biologically meaningful, and highly accurate model that (i) quickly forecasts a driver of downstream coagulation, thrombin concentration after tissue factor stimulation, using rapidly measurable concentrations of blood protein factors and (ii) determines the amounts of additional coagulation factors needed to rectify the predicted thrombin dynamics and potentially remedy ATC. We successfully demonstrate in vitro thrombin control consistent with the model. Compared to another model, we decreased the mean errors in two key trauma patient parameters: peak thrombin concentration after tissue factor stimulation and the time until this peak occurs. Our methodology helps to advance individualized resuscitation of trauma-induced coagulation deficits.

INTRODUCTION

Trauma is the leading cause of death and disability between the ages of 1 and 44 (*1*), with bleeding contributing to the vast majority of these deaths (*2*). Such hemorrhage is a clinical problem that is complicated by an endogenous biological response called acute traumatic coagulopathy (ATC) (*3*). ATC results in impaired coagulation, increased bleeding, greater transfusion needs, and a fourfold increase in mortality (*3*). After the initial phase of hypocoagulobility, ATC patients often dynamically transition to a hypercoagulable thrombotic state manifested by excessive clotting (*3*). The resulting deep vein thrombosis, myocardial infarction, stroke, and organ failure (*4*) all contribute to an extremely poor outcome in patients who survive their initial injuries.

Despite considerable research (*4*) on the molecular mechanisms of ATC, there remains a mechanistic and predictive knowledge gap that stems from an inadequate understanding of coagulation mechanisms after an injury and a lack of adequate prediction and real-time decision support for clinicians who care for the severely injured. These failings impede improvements to urgent resuscitation. Thus, there is a need to characterize coagulation mechanisms in trauma patients and to use this characterization to improve the precision of individual treatments.

In the absence of dynamic diagnostics and decision support, current trauma resuscitation practices (*4*) center on the nontargeted repair of the coagulation cascade (*5*) (Fig. 1A) and the production of its principal protein thrombin through the transfusion of large volumes of poorly characterized fresh-frozen plasma containing multiple clotting proteins and inhibitors in concentrations that vary from unit to unit. These urgent-care therapies indiscriminately actuate many interacting elements of the coagulation process, resulting in variable untargeted treatment for every patient and with every administration, which is further exacerbated by a lack of clarity about treatment effects on the patient's physiological and biological trajectories resulting from the missing diagnostics and decision support. Such blunt treatment is often either not enough (ATC and bleeding continue) or too much (thrombosis occurs). Both of these extremes contribute to dysregulated inflammation and poor outcomes (*4*). The mortality from massive transfusion remains at 40 to 70% in the best of trauma centers (*6*). Retrospective (*7*) and prospective (*8*) studies connect the blunt addition of fresh-frozen plasma to poor outcomes, even when the plasma is augmented with empiric ratios of platelets and red blood cells. Transfusion of fresh-frozen plasma is independently associated with a higher risk of multiple organ failure and poor outcomes in patients with hemorrhagic shock (*9*). Meanwhile, individual interventions consisting of personalized blood protein factor concentrations that are tailored to specific clotting perturbations have been shown to be beneficial (*4*), although no consensus yet exists on the amount and type of coagulation factors to administer. There is, however, a clinical desire for specific blood products to treat trauma coagulopathy (*10*). In sum, in an era of increasing personalized medicine, there is an urgent need for targeted, patient-specific trauma coagulation therapies.

Current diagnostics and decision support suffer from a dearth of patient-specific coagulation measurements. Although clinical practice uses several global markers [international normalized ratio (INR), partial thromboplastin time (PTT), prothrombin time (PT), platelet count, fibrinogen concentration, etc.] to diagnose the presence of ATC, these conventional coagulation tests are not enough to tailor a specific intervention and support only the decision to administer plasma or not. Cell-based viscoelastic tests are insufficiently predictive, and their use in resuscitation algorithms also results in nontargeted treatment. Moreover,

Personalized modulation of coagulation factors using a thrombin dynamics model to treat trauma-induced coagulopathy

Damon E. Ghetmiri[1], Mitchell J. Cohen[2] and Amor A. Menezes[1,3,4]✉

Current trauma-induced coagulopathy resuscitation protocols use slow laboratory measurements, rules-of-thumb, and clinician gestalt to administer large volumes of uncharacterized, non-tailored blood products. These one-size-fits-all treatment approaches have high mortality. Here, we provide significant evidence that trauma patient survival 24 h after hospital admission occurs if and only if blood protein coagulation factor concentrations equilibrate at a normal value, either from inadvertent plasma-based modulation or from innate compensation. This result motivates quantitatively guiding trauma patient coagulation factor levels while accounting for protein interactions. Toward such treatment, we develop a Goal-oriented Coagulation Management (GCM) algorithm, a personalized and automated ordered sequence of operations to compute and specify coagulation factor concentrations that rectify clotting. This novel GCM algorithm also integrates new control-oriented advancements that we make in this work: an improvement of a prior thrombin dynamics model that captures the coagulation process to control, a use of rapidly-measurable concentrations to help predict patient state, and an accounting of patient-specific effects and limitations when adding coagulation factors to remedy coagulopathy. Validation of the GCM algorithm's guidance shows superior performance over clinical practice in attaining normal coagulation factor concentrations and normal clotting profiles simultaneously.

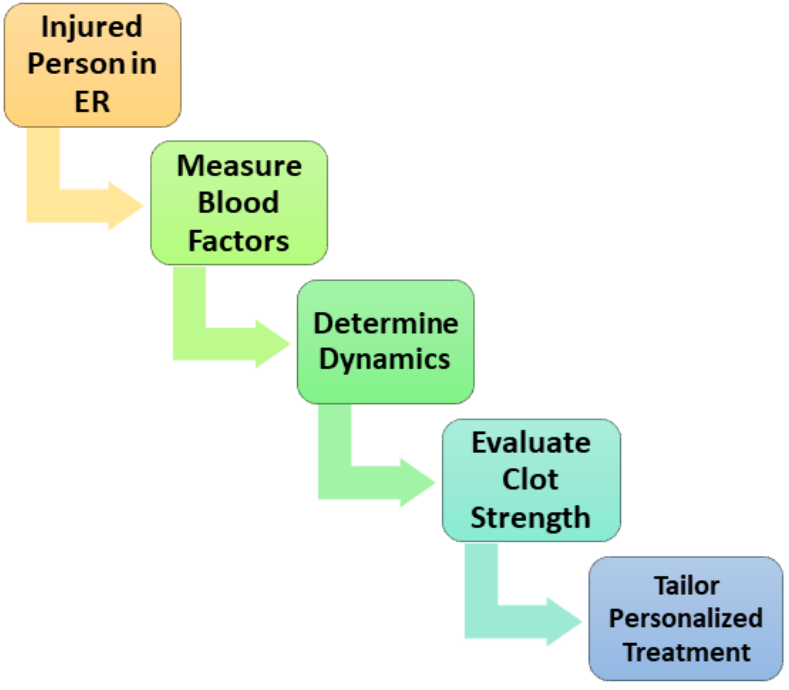
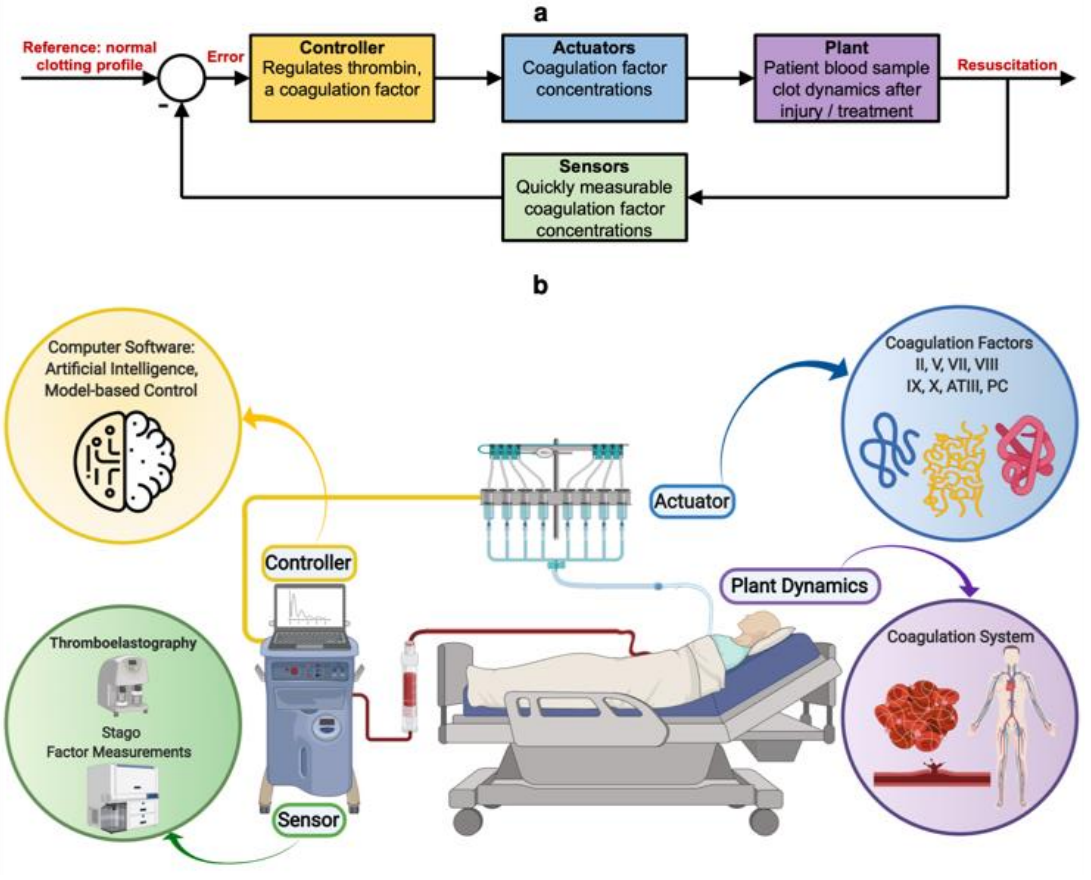
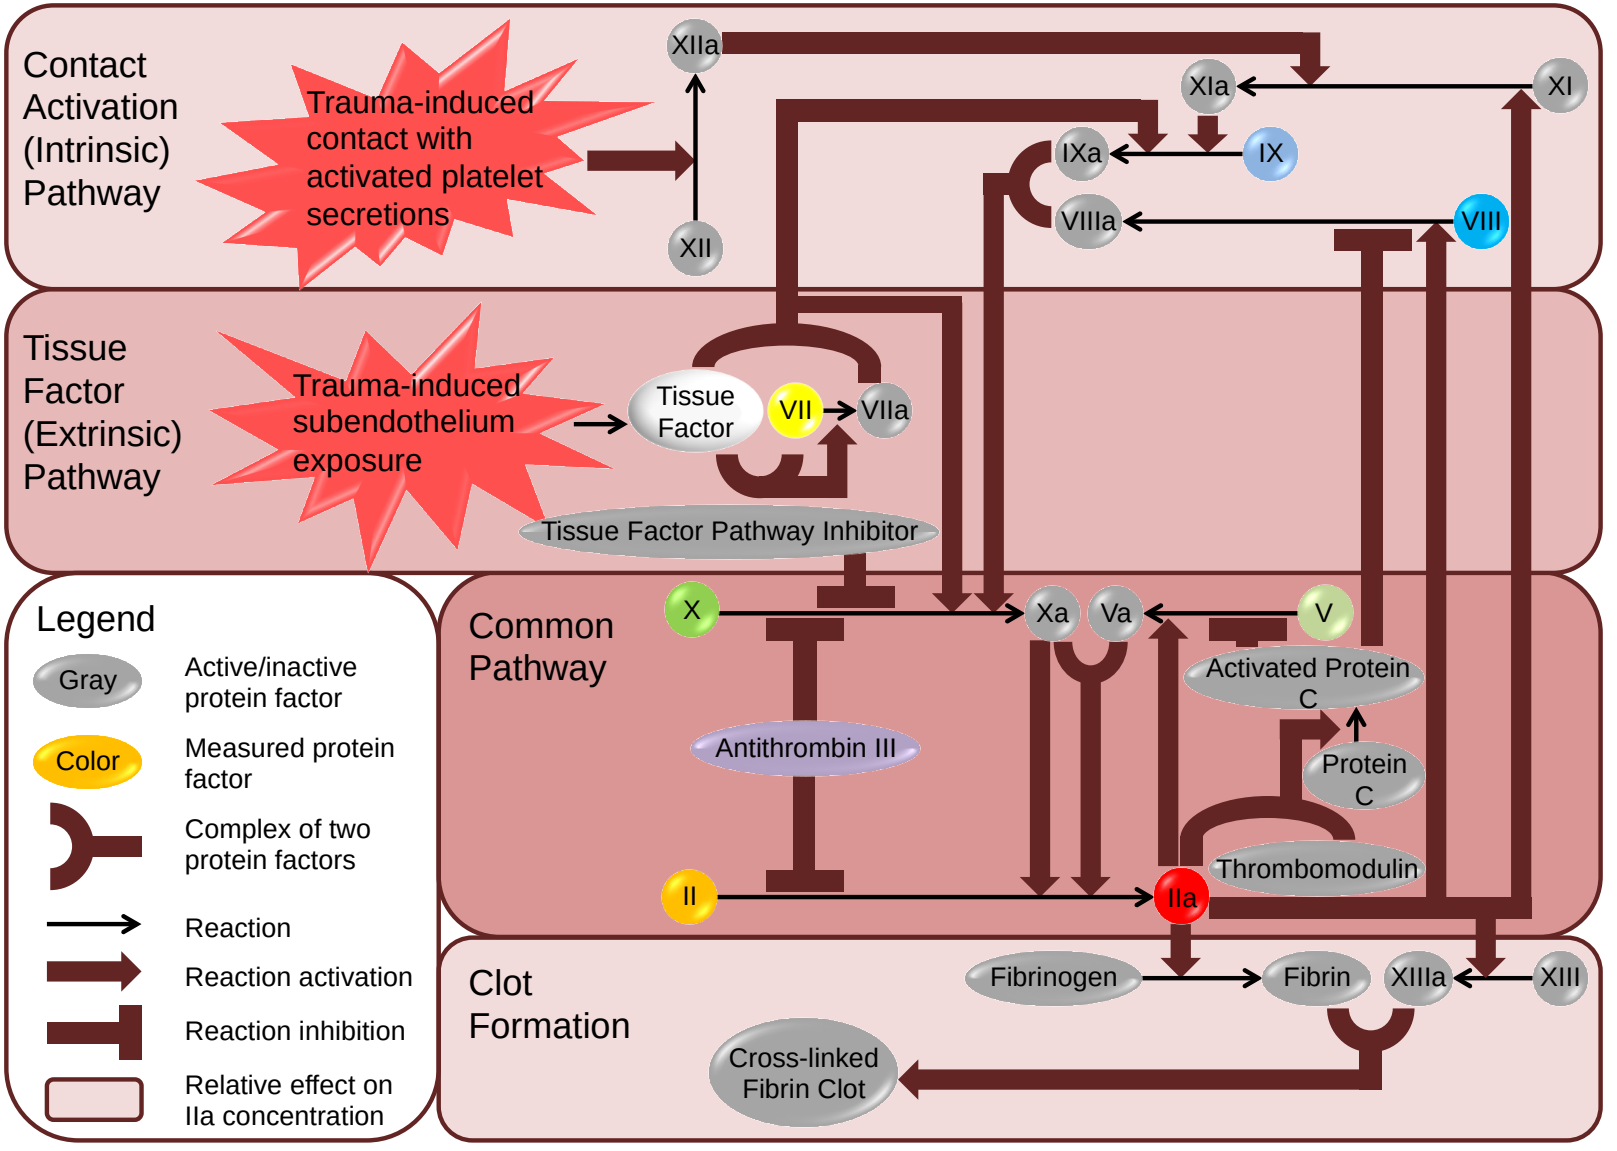
- 34 states, 43 chemical kinetic equations. No Protein C or Activated Protein C effects.
- Rate constants aggregated from 2002 literature.
- Initial conditions specify mean plasma concentrations for proteins, with tissue factor (TF) variable.

Solution: Personalized dynamic approach

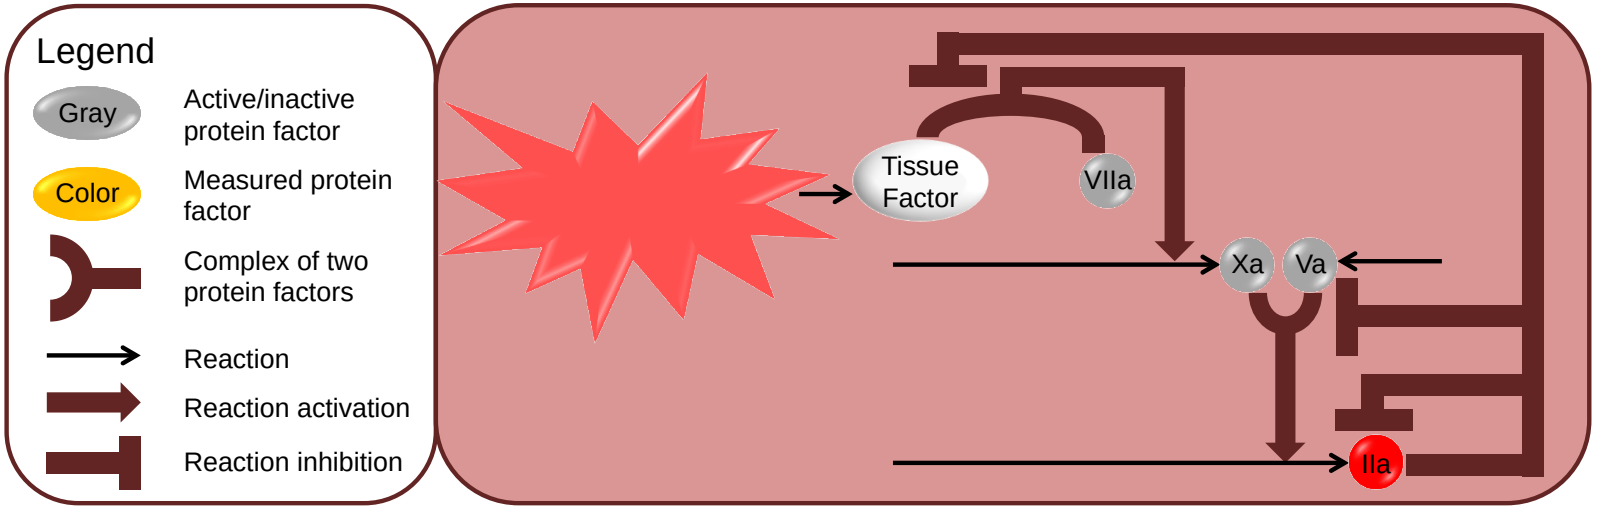




Current Understanding: Coagulation Cascade



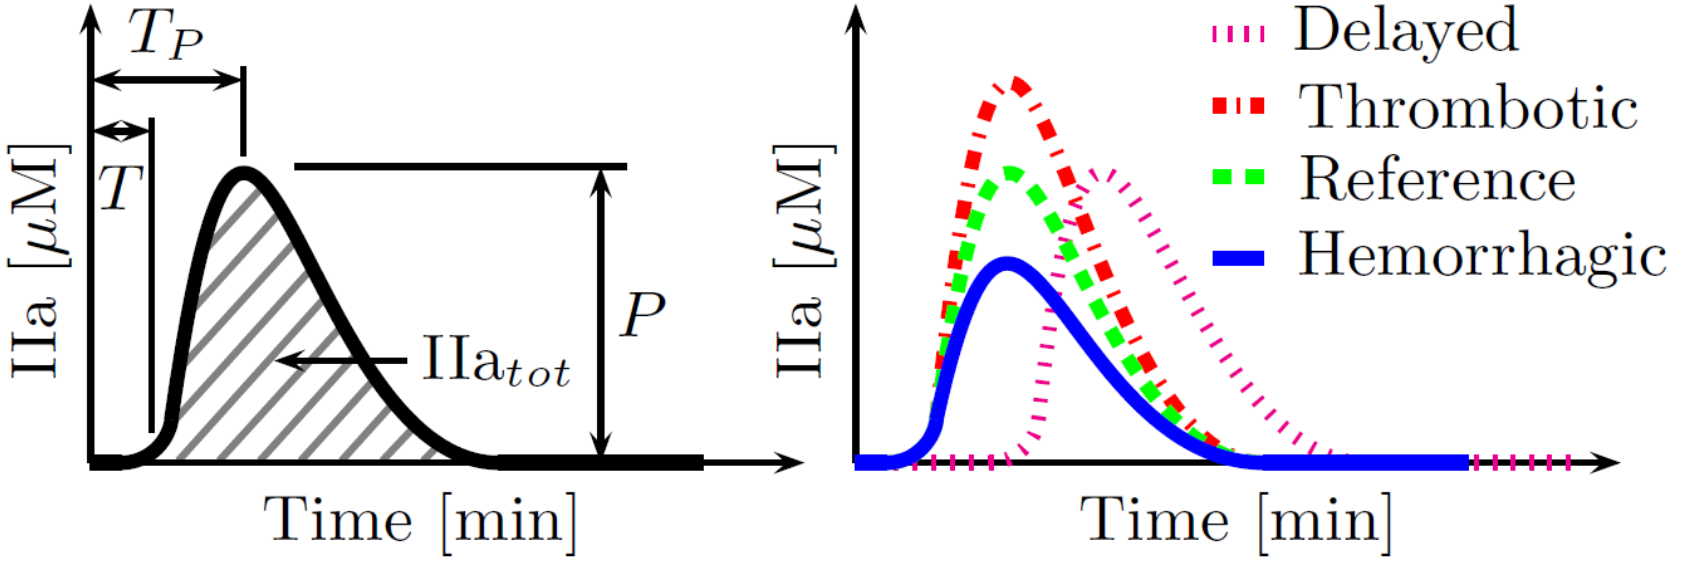
Claim: Possible to Simplify



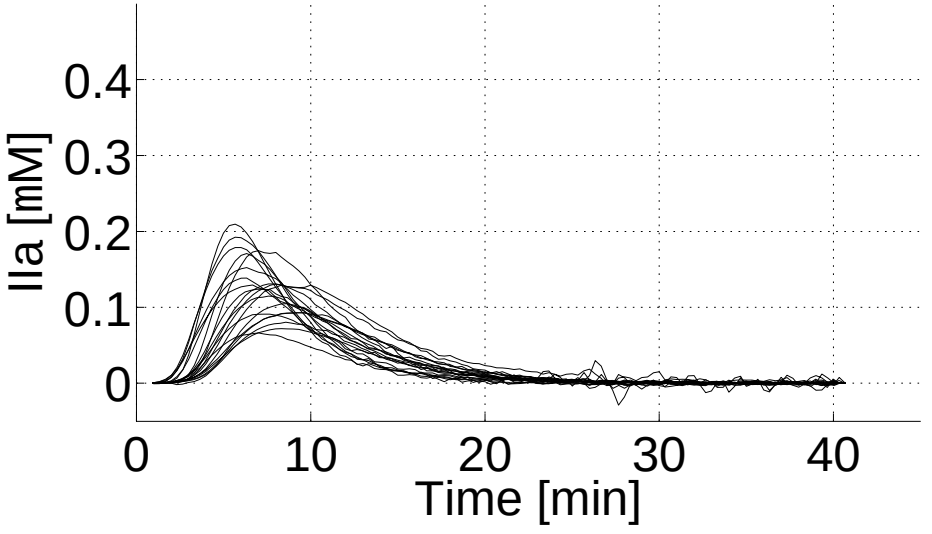
- Dynamical System Input: Tissue Factor
- Dynamical System Output: Thrombin
- Need an input-to-output measurement.

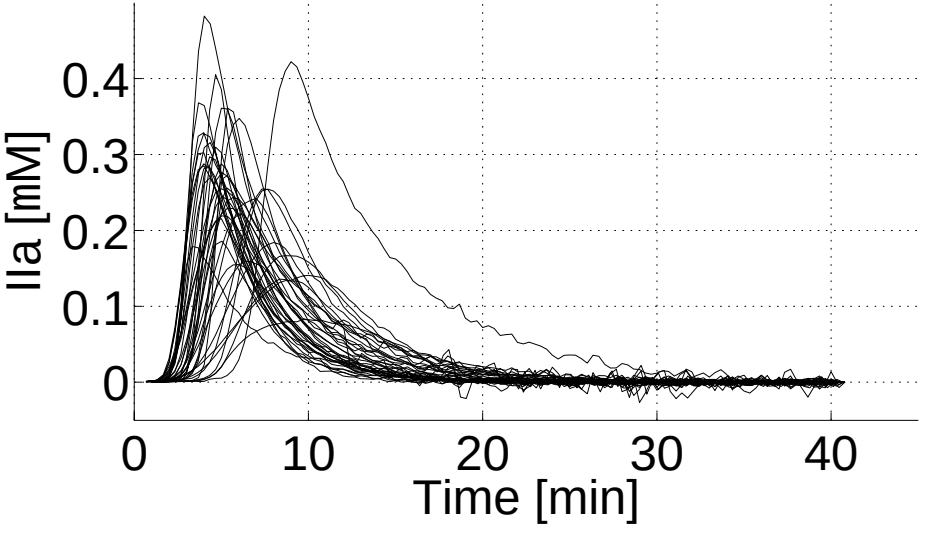
Thrombin Measurement

- The Calibrated Automated Thrombogram (CAT) is a fluorogenic assay that measures the time-history of thrombin generation in a blood sample upon the addition of (typically 5pM of) tissue factor.



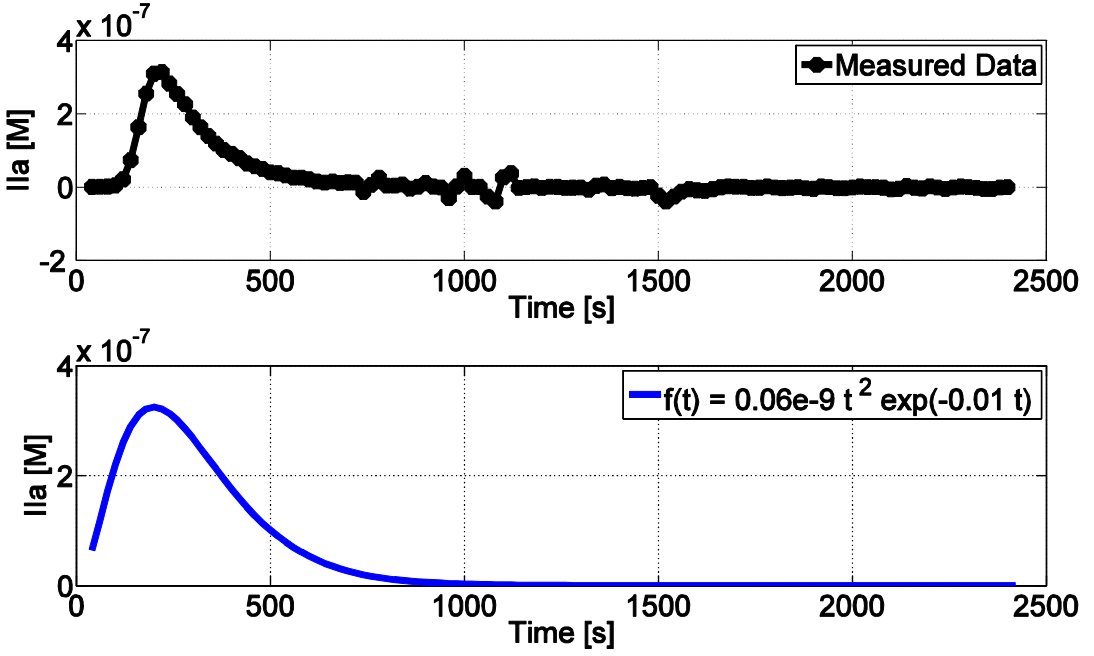
Normal vs. Trauma CATs





- Can we emulate trajectories with a single-input single-output thrombin dynamical system model with a separable delay for treatment guidance? What kind of model?

Building a Black-Box Model



- Can approximate a CAT peak.
- Suppose we choose the following non-delayed function as first approximation:

$$y(t) = \beta t^2 e^{-\alpha t}$$

- t^2 → three states.

- Look at output in frequency domain as the result of some dynamical system:

$$Y(s) = \frac{2\beta}{(s+\alpha)^3} = \frac{2\beta}{s^3 + 3\alpha s^2 + 3\alpha^2 s + \alpha^3}$$

Building a Black-Box Model: 3 states, 5 pars.

- Suppose input is a (unit) impulse, *U(s)* = 1:

$$\frac{Y(s)}{U(s)} = \frac{2\beta}{(s+\alpha)^3} = \frac{2\beta}{s^3 + 3\alpha s^2 + 3\alpha^2 s + \alpha^3}$$

- System transfer function, including delay:

$$\frac{Y(s)}{U(s)} = \frac{b}{s^3 + a_2 s^2 + a_1 s + a_0} e^{-sT}$$

Building a Black-Box Model: Traditional Form

$$\frac{Y(s)}{U(s)} = \left(\frac{Kp}{s+p}\right)\left(\frac{\omega_n^2}{s^2+2\zeta\omega_n s+\omega_n^2}\right)e^{-sT}$$

- Define

$\sigma = \zeta\omega_n$ and $\omega_d = \omega_n\sqrt{1-\zeta^2}$ (i.e., $\omega_n^2 = \sigma^2 + \omega_d^2$), and let

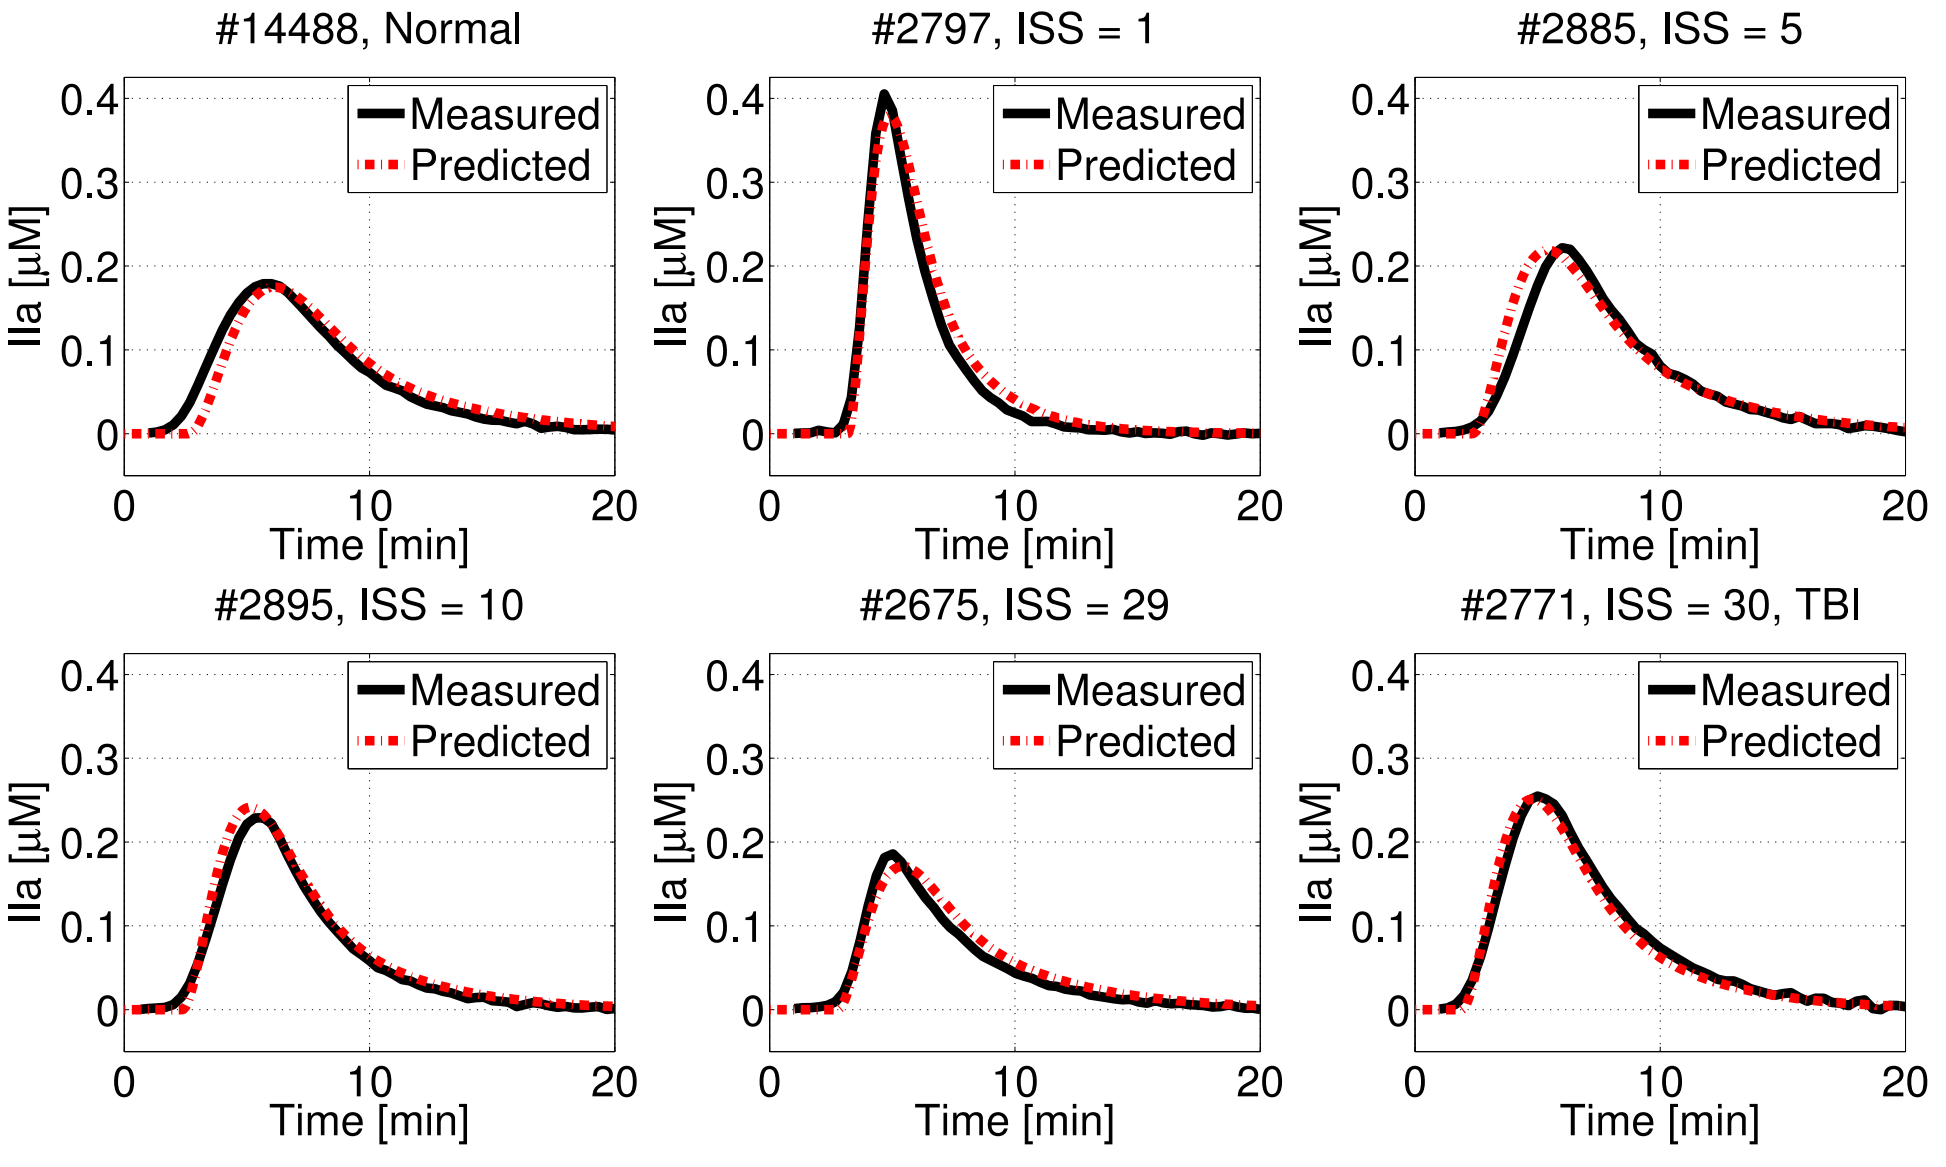
$A = \frac{Kp\omega_n^2}{p^2-2\zeta\omega_n p+\omega_n^2}$; $B = \frac{-Kp\omega_n^2}{p^2-2\zeta\omega_n p+\omega_n^2}$; $C = \frac{Kp\omega_n^2(p-2\zeta\omega_n)}{p^2-2\zeta\omega_n p+\omega_n^2}$;

$D = \left(B\cos\left(\omega_d\left(t-T\right)\right) + \frac{C-\sigma B}{\omega_d}\sin\left(\omega_d\left(t-T\right)\right)\right)$. Then each fitted time-delayed CAT unit impulse response is given by

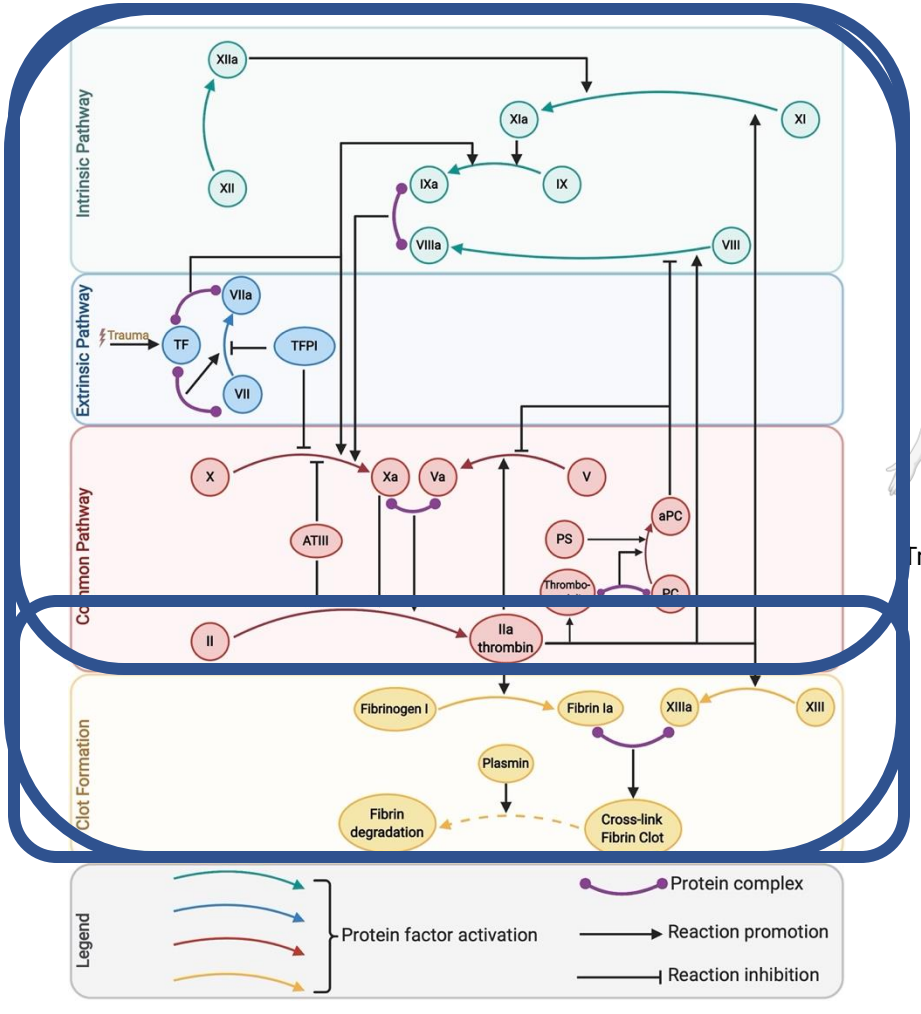
$$y(t) = \begin{cases} 0 & \text{if } t < T; \\ \left(Ae^{-p(t-T)} + De^{-\sigma(t-T)}\right)1(t-T) & \text{if } t \geq T, \end{cases}$$

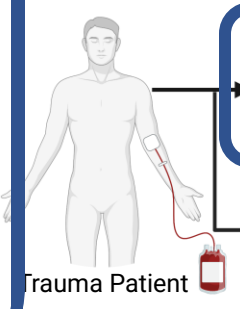
for some p, ζ, ω_n and T, computed from a_2, a_1, a_0 and T.

Performance



Extending to viscoelastic measures





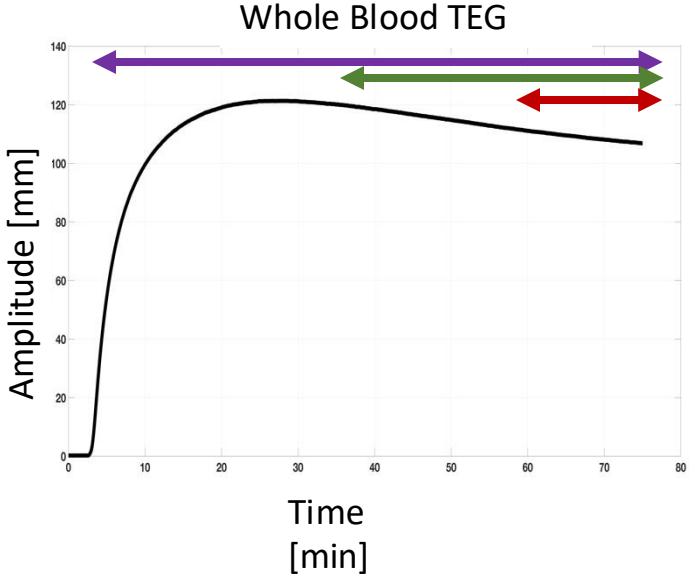
Factor Concentration to CAT → CAT to Plasma TEG → Plasma TEG to Whole Blood TEG → System Dynamics

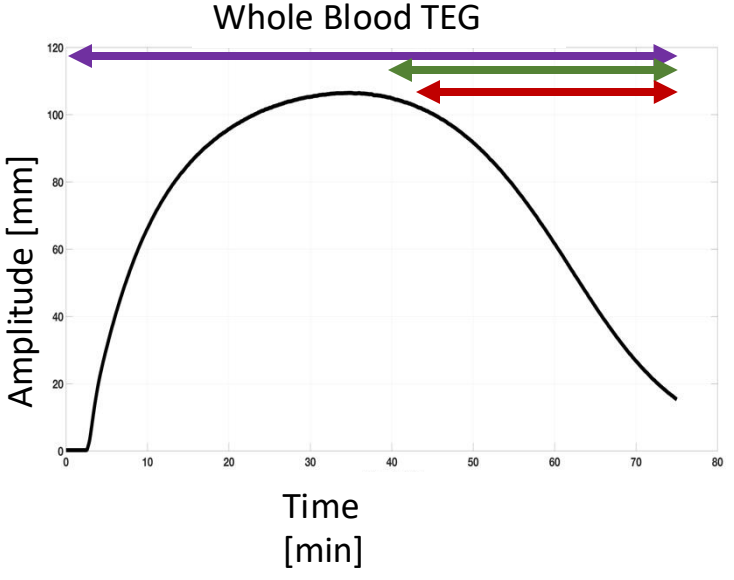
Factor Concentration to Whole Blood TEG → System Dynamics

Viscoelasticity of Whole Blood

Factor Concentrations to Whole Blood TEG

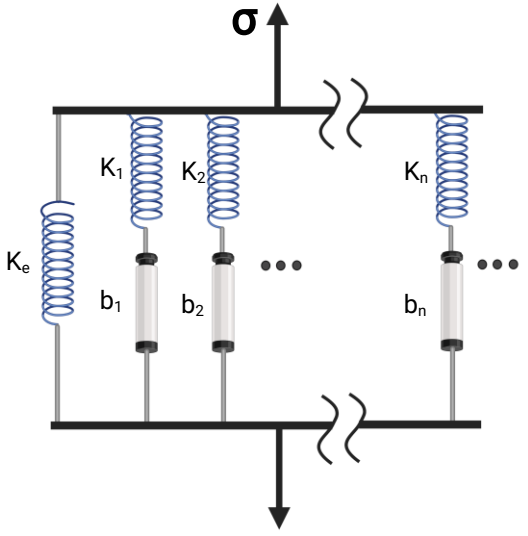
$$\frac{K_{n,1}}{s(K_{p,1}s+1)}e^{-sK_{d,1}} + \frac{-K_{n,2}}{s^2}e^{-sK_{d,2}} + \frac{-K_{n,3}}{s(K_{p,3}s+1)}e^{-sK_{d,3}}$$





Maxwell Model:
several parallel Maxwell elements (a spring and a damper connected in series)

$$\sigma(t) = \sigma_0\left(1 - e^{-\frac{1}{\tau}t}\right)$$

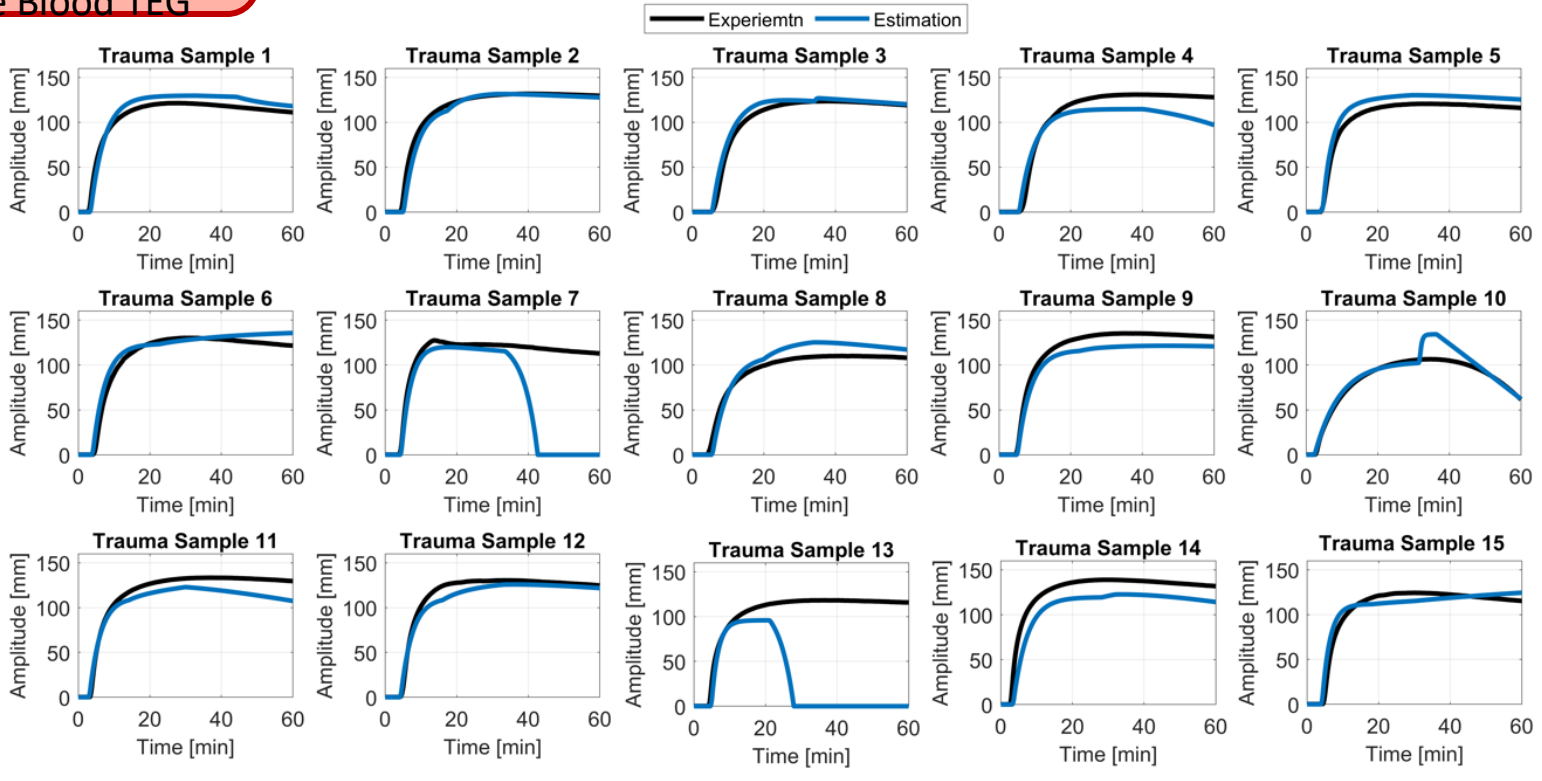


$$G(s) = \frac{P(s)}{Y(s)} = \frac{K_{n_p}}{s(K_p s + 1)} \times e^{-K_{dp}s} \xrightarrow{\text{Time domain}} g(t) = K_{n_p} - K_{n_p} e^{-\frac{1}{K_p}t}$$

Viscoelasticity of Whole Blood

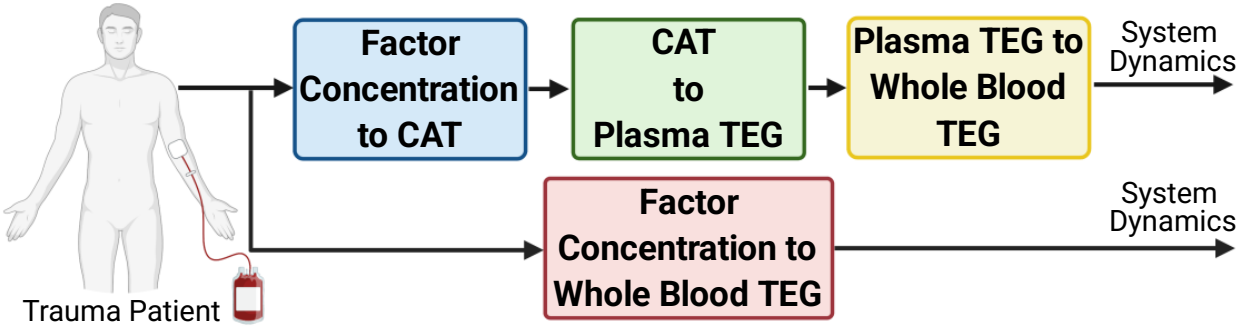
Factor Concentrations to Whole Blood TEG

TEG graph estimation using:
Coagulation factors II, V, VII, VIII, IX, X, ATIII, PC, D-dimer



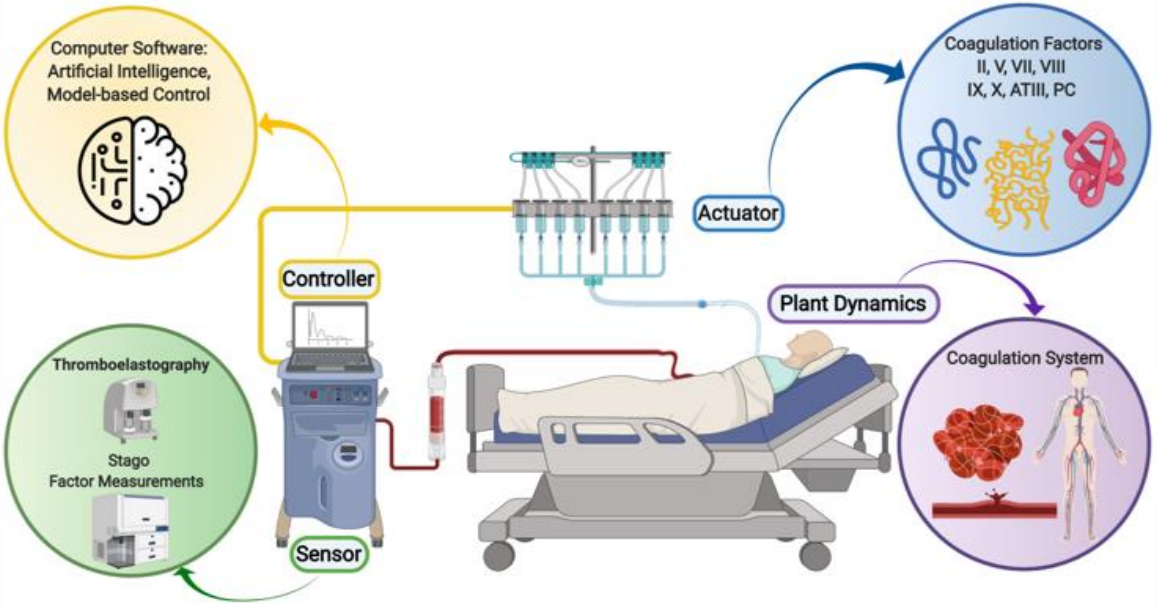
We can model blood clotting in silico

- a novel and simple model that captures the viscoelastic effects in plasma samples
- an estimate of the model output using easily-measurable coagulation factors
- a meaningful relationship between thrombin and this viscoelastic clot model
- a second new model to express viscoelastic clot formation, stabilization, and degradation in whole blood
- a comparison to the generalized Maxwell viscoelastic model



Future Work and Broad Impact

- Blood clot precision control using coagulation factors: obviating the use of generic treatment and improve patient outcome.
- Application to other coagulation disorders: hemophilia, von Willebrand disease, factor V Leiden, pulmonary embolism, deep vein thrombosis, stroke, and sickle cell disease.



Why does this matter?

- We have come a long way understanding and mitigating TIC.
- Our ‘one size fits all’ resuscitation has reduced mortality but misses the target often.
- While patients die early many are missed and morbidity is significant and important.
- Mitigating thromboinflammation can fix TIC and inflammation and improve outcomes.

We need (and can deliver) 4 things.

- An understanding of phenotypes of thromboinflammation after trauma (threat x)
- Cytoprotective agent(s) that can modulate coagulation and inflammation after trauma.
  - This can be agnostic and personalized.
  - Shelf stable resuscitation in a syringe.
- Prevention via a trauma vaccine
- Personalized medicine and optimized performance via measurement and modeling.
